CONFIDENTIAL — INVESTOR-2026

Abstract

This paper introduces Neural Oscillatory Signature Theory (NOST), a theoretical framework proposing that cognitive states can be inferred from linguistic output because neural oscillatory patterns systematically shape language production. The framework integrates established findings from cognitive neuroscience—particularly research on neural oscillations and their role in memory, attention, and executive function—with insights from psycholinguistics regarding the cognitive processes underlying language production. The central theoretical claim is that the statistical properties of linguistic output (lexical, syntactic, semantic, and temporal features) carry extractable information about the neural oscillatory configuration present during language generation. This paper articulates the theoretical foundations, proposes a formal relationship between oscillatory states and linguistic signatures, derives specific testable hypotheses, and discusses implications for cognitive assessment. The framework is offered as a theoretical contribution warranting empirical investigation rather than an established finding.

Keywords: neural oscillations, language production, cognitive assessment, linguistic analysis, memory retrieval, theoretical framework

Neural Oscillatory Signature Theory:
A Framework for Inferring Cognitive States from Linguistic Output

The relationship between mind and language has occupied philosophers and scientists for centuries. Language serves as the primary window through which internal mental states become externally observable. Yet despite significant advances in cognitive neuroscience and psycholinguistics, no comprehensive theoretical framework exists for systematically inferring cognitive states from the structural properties of linguistic output.

This paper proposes such a framework: Neural Oscillatory Signature Theory (NOST). The central claim is that neural oscillatory patterns—rhythmic electrical activity across distributed brain networks—systematically influence language production in ways that leave detectable traces in linguistic output. If this claim is correct, careful analysis of language could provide a non-invasive method for inferring the cognitive processes that generated it.

The present paper is explicitly theoretical. It integrates established empirical findings into a novel framework and derives testable predictions. Empirical validation remains to be conducted. The framework is offered to the scientific community for scrutiny, critique, and empirical investigation.

Theoretical Foundations

Neural Oscillations and Cognitive Function

Neural oscillations—rhythmic fluctuations in the electrical activity of neuronal populations—have emerged as fundamental to cognitive function (Buzsáki, 2006; Buzsáki & Draguhn, 2004). Research over the past three decades has established consistent associations between oscillatory activity in specific frequency bands and distinct cognitive processes.

CONFIDENTIAL — INVESTOR-2026

Delta oscillations (0.5–4 Hz) predominate during deep sleep and have been implicated in motivational processes and the detection of salient stimuli during waking states (Knyazev, 2012). Theta oscillations (4–8 Hz), generated prominently in the hippocampus, are critically involved in episodic memory encoding and retrieval (Kahana et al., 2001; Nyhus & Curran, 2010). The theta rhythm appears to coordinate the reactivation of distributed memory representations and facilitates communication between hippocampus and neocortex during memory operations (Colgin, 2013).

Alpha oscillations (8–13 Hz) are associated with attentional processes, particularly the inhibition of task-irrelevant information (Klimesch, 2012). Beta oscillations (13–30 Hz) have been linked to motor planning, working memory maintenance, and the preservation of current cognitive states (Engel & Fries, 2010). Gamma oscillations (30–100 Hz) are implicated in perceptual binding, attentional selection, and the active processing of information in working memory (Fries, 2009).

Critically, these oscillatory bands do not operate in isolation. Cross-frequency coupling—particularly the modulation of gamma amplitude by theta phase—has emerged as a mechanism for integrating information across temporal scales (Canolty & Knight, 2010). Theta-gamma coupling in the hippocampus and medial temporal lobe is reliably observed during successful episodic memory retrieval (Fell & Axmacher, 2011) and appears to coordinate the binding of distributed representations into coherent memory traces.

Language Production and Cognitive Processes

Language production is not a simple translation of thought into words. Rather, it involves a cascade of cognitive processes: conceptualization (determining what to express), formulation (lexical selection, grammatical encoding, phonological encoding), and articulation (motor

CONFIDENTIAL — INVESTOR-2026

execution) (Levelt, 1989; Levelt et al., 1999). Each stage draws upon distinct cognitive resources and, by implication, distinct neural systems.

Critically for the present framework, the source of the content being verbalized influences the cognitive processes engaged during production. Describing a remembered personal experience engages episodic memory retrieval—a process dependent on hippocampal theta oscillations and theta-gamma coupling (Nyhus & Curran, 2010). In contrast, generating a novel narrative without episodic grounding relies more heavily on working memory and executive functions—processes associated with prefrontal beta oscillations (Engel & Fries, 2010).

This distinction is empirically supported. Research on reality monitoring (Johnson & Raye, 1981) has established that memories of perceived events differ systematically from memories of imagined events in their phenomenological qualities. Perceived memories contain more perceptual, spatial, and temporal detail, while imagined memories contain more information about cognitive operations. Subsequent work has shown these differences manifest in verbal descriptions: accounts of actual experiences contain more sensory and contextual detail than fabricated accounts (Vrij, 2008).

The Linking Hypothesis

NOST proposes a specific mechanistic link between these two bodies of research. The framework rests on the following premises:

Premise 1: Different cognitive processes engage different neural oscillatory configurations. This premise is well-supported by the cognitive neuroscience literature reviewed above. Episodic retrieval, working memory maintenance, attentional control, and semantic access each have characteristic oscillatory signatures.

CONFIDENTIAL — INVESTOR-2026

Beverly Index LLC | Access Code: INVESTOR-2026 | Unauthorized distribution prohibited

CONFIDENTIAL — INVESTOR-2026

Premise 2: Neural oscillatory states influence the processing dynamics of language production. Evidence supports this premise. Oscillatory activity has been shown to modulate processing speed, information integration, and resource allocation during cognitive tasks (Klimesch et al., 2007). Language production, as a cognitive process, should be similarly influenced.

Premise 3: Processing dynamics during language production leave traces in the statistical properties of linguistic output. This premise is supported by psycholinguistic research showing that cognitive load, retrieval difficulty, and processing fluency affect measurable properties of speech and text, including lexical diversity, syntactic complexity, speech rate, pause patterns, and error rates (Bock, 1996; Goldman-Eisler, 1968).

Premise 4: Therefore, the statistical properties of linguistic output carry information about the neural oscillatory state during production. This final premise follows logically from the first three. If oscillatory states influence processing dynamics, and processing dynamics influence linguistic output, then linguistic output carries information about oscillatory states.

The Formal Framework

The relationship proposed by NOST can be expressed formally. Let Ψ represent the extractable cognitive signature in linguistic output—the pattern of statistical features that carries information about cognitive state. Let Ω represent the neural oscillatory configuration during language production—the distribution of power and coupling relationships across frequency bands. Let Λ represent the linguistic encoding function—the systematic (though complex and probabilistic) mapping from oscillatory states to linguistic features.

The core theoretical claim can be expressed as:

$$\Psi = f(\Omega, \Lambda)$$

CONFIDENTIAL — INVESTOR-2026

Beverly Index LLC | Access Code: INVESTOR-2026 | Unauthorized distribution prohibited

CONFIDENTIAL — INVESTOR-2026

More specifically, if we treat both the cognitive signature and oscillatory state as vectors of measurable quantities, and if the encoding function is approximately linear over relevant ranges, this simplifies to:

$$\Psi \approx \Lambda \cdot \Omega$$

This formulation makes explicit that the cognitive signature is a transformed representation of the oscillatory state. The encoding function Λ incorporates individual differences (personal linguistic habits, vocabulary, syntactic preferences), contextual factors (topic, audience, register), and the systematic but imperfect relationship between neural processes and their linguistic manifestations.

This formal expression is offered as a conceptual framework, not a claim of mathematical precision. The actual relationship is undoubtedly more complex, involving nonlinearities, noise, and multiple mediating factors. The utility of the formal expression is to make explicit the theoretical commitment: that there exists a systematic, extractable relationship between oscillatory states and linguistic features.

Predicted Oscillatory-Linguistic Correspondences

If NOST is correct, specific oscillatory patterns should correspond to specific linguistic features. The following correspondences are proposed based on the established functions of each oscillatory band:

Theta-band signatures (episodic memory engagement). Elevated theta activity, particularly when coupled with gamma oscillations, characterizes episodic memory retrieval. NOST predicts that language produced during genuine episodic retrieval should exhibit: (a) elevated sensory language—higher rates of visual, auditory, tactile, olfactory, and gustatory descriptors; (b) temporal specificity—specific temporal markers and appropriate tense usage; (c)

CONFIDENTIAL — INVESTOR-2026

Beverly Index LLC | Access Code: INVESTOR-2026 | Unauthorized distribution prohibited

CONFIDENTIAL — INVESTOR-2026

spatial grounding—spatial references and environmental details; (d) first-person perspective—self-referential framing and personal perspective markers; and (e) emotional integration—affect terms integrated naturally into the narrative.

Beta-band signatures (working memory and construction). Elevated beta activity characterizes working memory maintenance and executive control. NOST predicts that language produced during active construction should exhibit: (a) logical sequencing—explicit logical connectives and chronological organization; (b) reduced sensory detail—fewer spontaneous sensory references; (c) hedging and qualification—more hedging language and markers of cognitive effort; (d) script-based content—more generic, schematic content; and (e) monitoring markers—more self-corrections and metalinguistic comments.

Cross-frequency coupling signatures. The coupling between theta and gamma oscillations indexes memory binding. NOST predicts that stronger coupling should correlate with: (a) greater narrative coherence; (b) better integration of details within scenes; and (c) richer spontaneous elaboration.

Testable Hypotheses

A theoretical framework is valuable to the extent it generates falsifiable predictions. NOST generates the following specific hypotheses:

Hypothesis 1 (concurrent validity): If linguistic features are recorded simultaneously with EEG during narrative production, the linguistic features predicted to correspond with specific oscillatory patterns will show statistically significant correlations with power in the corresponding frequency bands. Specifically, sensory language density should positively correlate with theta power and theta-gamma coupling; logical connective density should

CONFIDENTIAL — INVESTOR-2026

Beverly Index LLC | Access Code: INVESTOR-2026 | Unauthorized distribution prohibited

CONFIDENTIAL — INVESTOR-2026

positively correlate with beta power; hedging language should positively correlate with beta power and negatively correlate with theta-gamma coupling.

Hypothesis 2 (discriminant validity): Linguistic analysis of narratives describing verified autobiographical events will show significantly different feature profiles compared to deliberately fabricated narratives, with the direction of differences consistent with NOST predictions. Autobiographical narratives should show higher sensory language density; fabricated narratives should show higher rates of logical connectives and chronological markers.

Hypothesis 3 (individual calibration): Within-subject designs comparing the same individual's autobiographical and fabricated narratives will show larger effect sizes than between-subject designs, reflecting the importance of individual baseline differences in linguistic style.

Hypothesis 4 (cross-linguistic generalization): If NOST captures a fundamental cognitive-linguistic relationship, the predicted correspondences should hold across languages, though the specific linguistic features indexing each correspondence may vary by language structure.

Hypothesis 5 (clinical populations): Populations with documented alterations in oscillatory activity (e.g., hippocampal damage affecting theta rhythms, prefrontal dysfunction affecting beta rhythms) should show corresponding alterations in the linguistic features predicted by NOST.

Scope and Limitations

Several important limitations must be acknowledged.

CONFIDENTIAL — INVESTOR-2026

Beverly Index LLC | Access Code: INVESTOR-2026 | Unauthorized distribution prohibited

CONFIDENTIAL — INVESTOR-2026

First, the encoding function Λ is theorized but not specified. NOST proposes that a systematic mapping exists between oscillatory states and linguistic features but does not specify the precise mathematical form of this mapping. Determining this function is an empirical task.

Second, linguistic output is multiply determined. Cognitive state is only one influence on language production. Individual differences, social context, communicative goals, and linguistic conventions all contribute. NOST does not claim that cognitive state is the sole or even primary determinant of linguistic features—only that it is a detectable influence.

Third, the framework as presented focuses on the contrast between episodic retrieval and active construction. This is a simplification. Actual language production involves complex, dynamic interactions among multiple cognitive processes.

Fourth, NOST is agnostic about whether linguistic signatures can be voluntarily manipulated. It is possible that individuals could learn to produce linguistic features inconsistent with their cognitive states.

Fifth, all claims in this paper are theoretical. No empirical validation of the specific hypotheses has been published. Preliminary clinical application of analysis methods based on these principles is underway, but systematic validation studies have not been completed. The framework is offered for scientific investigation, not as established fact.

Sixth, any application involving inference about mental states from linguistic analysis raises ethical concerns regarding privacy, consent, and potential misuse. These considerations must be addressed as the framework develops.

Relation to Existing Research

NOST intersects with several existing research traditions. Johnson and colleagues' work on reality monitoring (Johnson & Raye, 1981; Johnson et al., 1993) established that perceived

CONFIDENTIAL — INVESTOR-2026

Beverly Index LLC | Access Code: INVESTOR-2026 | Unauthorized distribution prohibited

CONFIDENTIAL — INVESTOR-2026

and imagined events differ in their memorial characteristics. NOST provides a mechanistic account: different oscillatory configurations during encoding lead to different memory representations with different linguistic manifestations during retrieval.

Research on verbal credibility assessment, including Criteria-Based Content Analysis and Reality Monitoring approaches (Vrij, 2008), has identified linguistic features distinguishing truthful from fabricated accounts. However, this literature developed largely without reference to cognitive neuroscience mechanisms. NOST offers theoretical grounding for why these features should discriminate: they reflect different underlying cognitive processes with different oscillatory signatures.

Neurolinguistic research has examined oscillatory activity during language comprehension and production (Meyer et al., 2016; Piai et al., 2015). This work has generally focused on within-task dynamics rather than how oscillatory states influence output characteristics. NOST extends this by proposing that oscillatory states leave extractable traces in the linguistic product.

Conclusion

Neural Oscillatory Signature Theory proposes that cognitive states leave extractable signatures in linguistic output because neural oscillatory patterns systematically shape language production. The framework integrates established findings from cognitive neuroscience and psycholinguistics into a novel theoretical synthesis.

The central claim—that linguistic analysis can provide information about the oscillatory configuration during language production—is offered as a testable hypothesis, not an established fact. The framework makes specific, falsifiable predictions that can be evaluated through empirical research.

CONFIDENTIAL — INVESTOR-2026

If validated, NOST would provide a theoretical foundation for understanding how the structure of language reflects the structure of thought. If falsified, the specific correspondences proposed would need revision or the framework abandoned. Either outcome would advance scientific understanding.

The framework is offered to the research community for scrutiny and empirical investigation. The author welcomes collaboration with researchers interested in testing these predictions.
